

Please replace the paragraph beginning at ~~page 5, line 8~~ with the following rewritten paragraph:

Once the surface of the substrate is cleaned, a layer of a wet bonding material such as a primer is applied to the surface of the substrate. The wet bonding material may include one or more additives which change or enhance one or more characteristics of the wet bonding material. For example, in one embodiment, the wet bonding material includes an ultraviolet light cure resin. In another embodiment, the wet bonding material includes an electron beam cure resin. It should also be appreciated that the bonding material may be any suitable bonding material or agent. The bonding material layer is formulated to also improve the bonding capabilities of the subsequent coating layer or layers applied to the surface of the substrate in addition to retaining the particles. The layer of wet bonding material is preferably applied uniformly so as to avoid forming a thick layer, which is thicker than what is necessary or required, and avoid drippings which may detract from the bonding ability to the substrate. Please replace the paragraph beginning at ~~page 8, line 24~~ with the following rewritten paragraph:

In another embodiment, specially treated, uniform plastic particles are applied to a surface of a substrate. The plastic particles can be pre-treated PTFE, ultra high molecular weight polyethylene (UHMW) and/or PE or another suitable material ~~and are~~ applied to the wet bonding material on the surface of the substrate. The particles are irradiated or processed with an electron beam which causes changes to the surface of the particles, allowing them to wet more easily and to sink into the wet bonding material layer, instead of remaining on the top of the material bonding layer. Therefore, the plastic particles are strongly bonded to the layer and not easily dislodged from the surface. This process thereby enables the plastic particle layer to last longer.

It should be appreciated that any suitable non-stick material may be applied to the anti-microbial particles. It should also be appreciated that any other suitable top coating may be applied to the anti-microbial particles. Once the top coating is applied to the anti-microbial particles, the coated electrode is cured in a suitable curing oven, furnace or by a suitable curing method or process as described above. The oven dries, sinters or cures the coated electrode and thereby enhances the adhesion of the coatings on the electrode, which causes the coatings and dry anti-microbial particles to adhere to the surface of the electrode 1102. In this embodiment, the top coating is applied to the electrode so that at least a portion of the anti-microbial particles are exposed at the surface of the coated electrode 1102. Additionally, the top coating is not applied to the anti-microbial particles underneath at least a portion of the insulative material. This fully exposes the anti-microbial particles underneath this portion of the insulative material and prevents harmful organisms from getting underneath the insulative material and growing or cultivating. Both the coating on the electrode and the fully exposed anti-microbial particles underneath the insulative material minimizes and/or prevents bacteria and other harmful organisms from remaining and growing on the surface of the electrode 1102 by killing a substantial portion of these organisms when the organisms come in contact with the anti-microbial particles. It should be appreciated that the anti-microbial particles are uniformly and completely exposed at the surface of the electrode so that any organisms that contact the surfaces of the electrode contact the exposed anti-microbial particles. The coatings may be applied to the surface of the electrode 1102 to a desired thickness 1122 as shown in Fig. 13D. In one embodiment, the primer coating, the anti-microbial particles, and the top coating are repeatedly applied to the surface of the electrode until a designated or desired thickness is achieved. After the desired thickness is achieved, the coated electrode is at least partially cured in a suitable curing oven. It should be appreciated that any suitable number of coatings may be applied to the surface of the electrode. It should also be appreciated that any suitable mixture or combination of coatings such as multiple
